1 Introduction

In this appendix the detailed SEM results are provided from applying different models to the data of the low and medium-altitude hay meadows (EUNIS R2.2) and the mountain hay meadows (R2.3). As measure of species richness either the total species richness or the number of the target species were used.

2 Main model

In this chapter we applied the data to the conceptual model as described in the section *conceptual model* in the main body of the manuscript for a detailed description of the model. The main model is depicted as a causal diagram in the following figure.

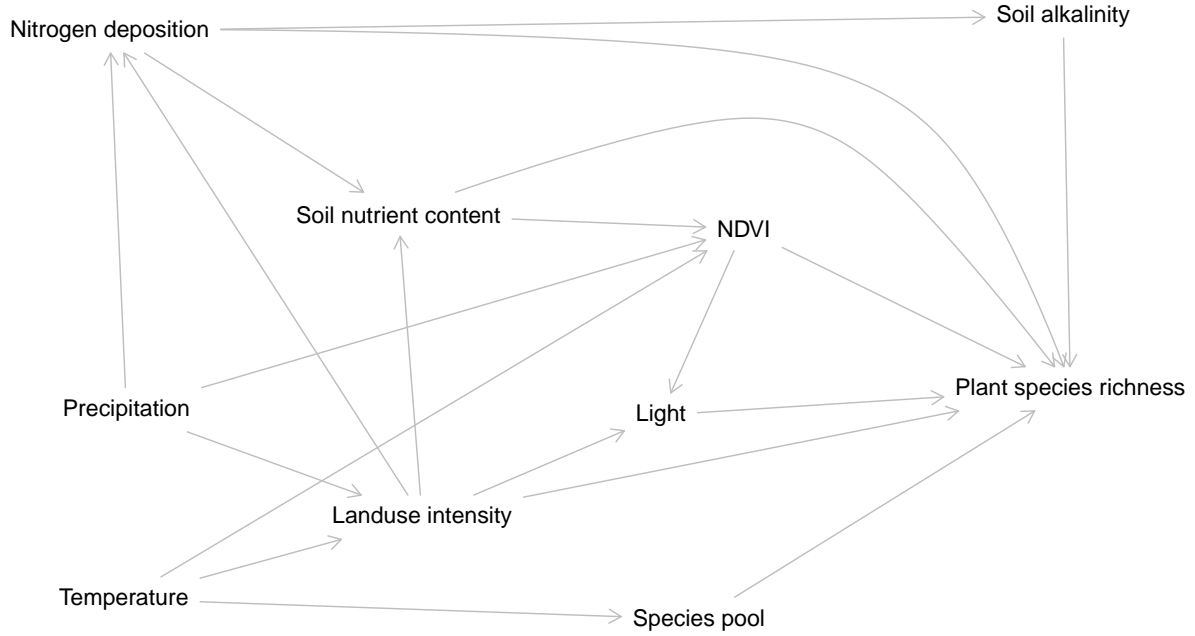

Figure 1: Conceptual model used in the SEM.

Based on the conceptual model the following equations were used to analyse the data:

$$Plant\ species\ richness = Nitrogen\ deposition + Soil\ alkalinity + Soil\ nutrient\ content + NDVI + Light + Landuse\ intensity + Species\ pool \quad (1)$$

$$Soil\ alkalinity = Nitrogen\ deposition \quad (2)$$

$$Soil\ nutrient\ content = Nitrogen\ deposition + Landuse\ intensity \quad (3)$$

$$NDVI = Soil\ nutrient\ content + Precipitation + Temperature \quad (4)$$

$$Light = NDVI + Landuse\ intensity \quad (5)$$

$$Nitrogen\ deposition = Precipitation + Landuse\ intensity \quad (6)$$

$$Landuse\ intensity = Temperature + Precipitation \quad (7)$$

$$Species\ pool = Temperature \quad (8)$$

These formulas were implemented and applied to the data using the R-package **brms** (Bürkner 2021). The results are shown in the following tables. The same results are also depicted in Figure 3 in the main body of the manuscript.

Table 1: SEM Results from applyig the structural equation model for the **total species richness** applied to the to the data of the **low and medium-altitude hay meadows** (EUNIS R2.2).

3 Effect of monitoringprogramm

While in the biodiversity monitoring Switzerland (BDM) two visits per year are conducted to survey the presence and absence of plants, for he agricultural species and habitats monitoring program (ALL-EMA) and the monitoring that was implemented to infer the effectiveness of habitat conservation in Switzerland (WBS) only a single visit was conducted. The monitoring programm may thus affect the number of recorded species. We thus added the variable BDM, which indicates weather the sampling site was part of the (BDM = 1). Otherwise the conceptual model is the same as the main model:

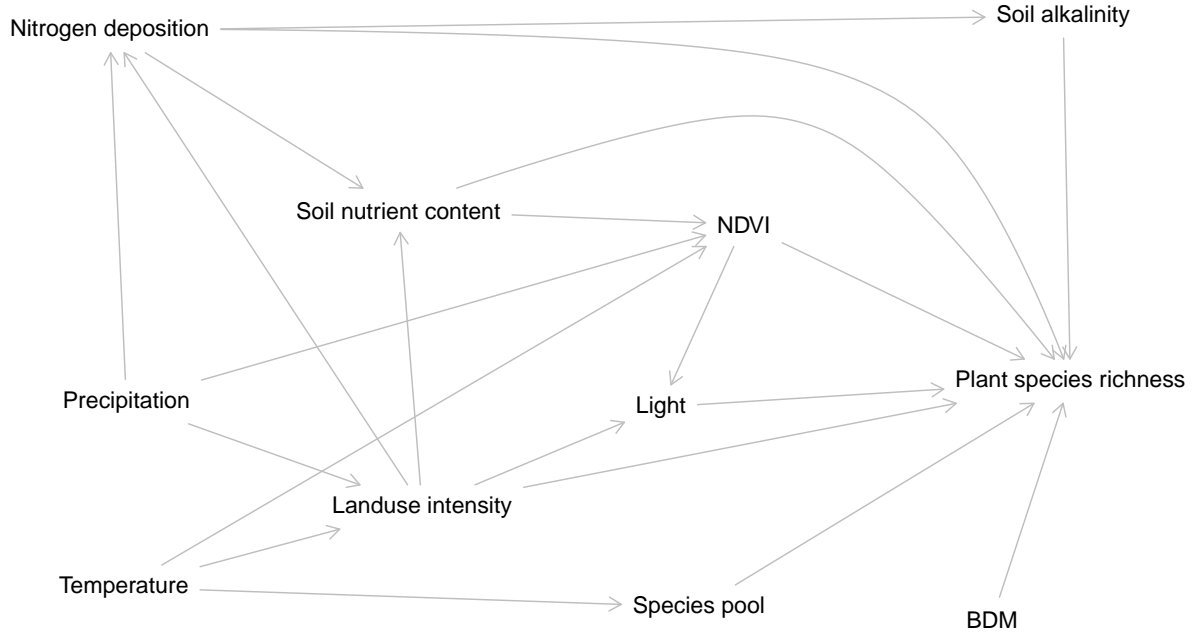

Figure 2: Conceptual model used in the SEM.

Based on the conceptual model the following equations were used to analyse the data:

$$\text{Plant species richness} = \text{Nitrogen deposition} + \text{Soil alkalinity} + \text{Soil nutrient content} + \text{NDVI} + \text{Light} + \text{Landuse intensity} + \text{Species pool} + \text{BDM} \quad (9)$$

$$\text{Soil alkalinity} = \text{Nitrogen deposition} \quad (10)$$

$$\text{Soil nutrient content} = \text{Nitrogen deposition} + \text{Landuse intensity} \quad (11)$$

$$\text{NDVI} = \text{Soil nutrient content} + \text{Precipitation} + \text{Temperature} \quad (12)$$

$$\text{Light} = \text{NDVI} + \text{Landuse intensity} \quad (13)$$

$$\text{Nitrogen deposition} = \text{Precipitation} + \text{Landuse intensity} \quad (14)$$

$$\text{Landuse intensity} = \text{Temperature} + \text{Precipitation} \quad (15)$$

$$\text{Species pool} = \text{Temperature} \quad (16)$$

These formulas were implemented and applied to the data. The results are shown in the following tables.

Table 5: SEM Results from applyig the conceptual model of Fig. 2 for the **total species richness** applied to the to the data of the **low and medium-altitude hay meadows** (EUNIS R2.2).

4 Starting model

We started the analyses with a simpler model that is shown in the following graph. Only later we adapted this starting model based on the graphical model by DeMalach (2018) to the main model. The results of this simpler model probably has shaped our conclusion. Accordingly, we also present the results of this model here. This simpler model is a selection of the variables from the main model, except for Inclination. In this simpler model we used inclination of the terrain at the sampling site as a proxi for the landuse intensity (higher inclination = lower landuse intensity). In the main model we then replaced inclination by the landuse intensity index.

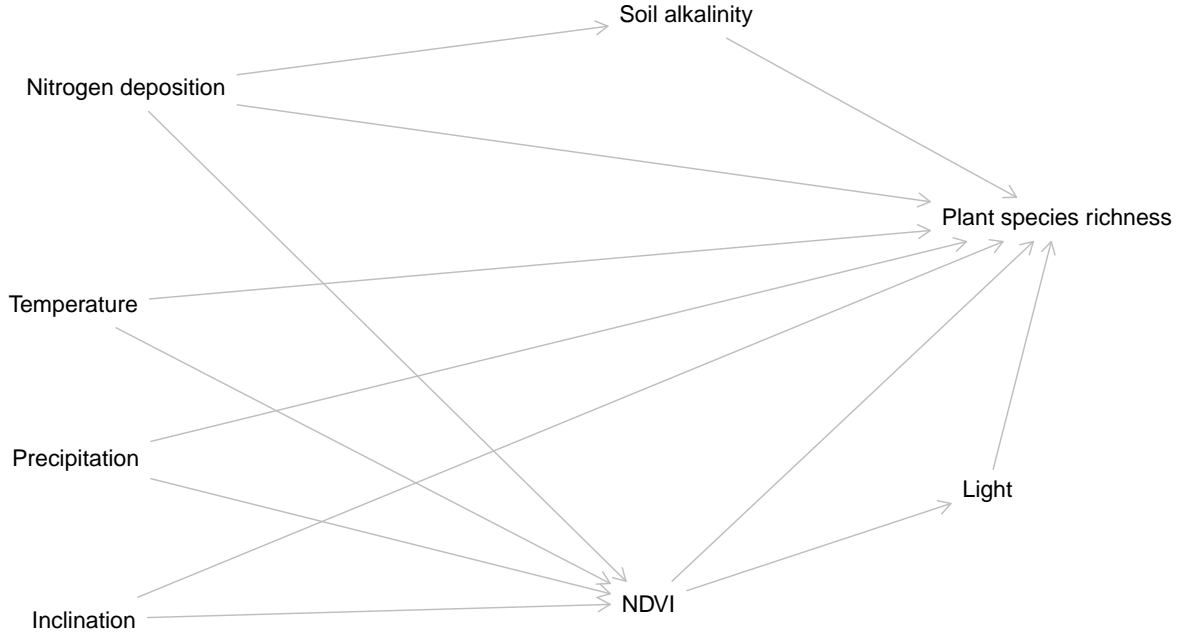

Figure 3: Conceptual model used in the SEM.

Based on the conceptual model the following equations were used to analyse the data:

$$Plant\ species\ richness = Nitrogen\ deposition + Soil\ alkalinity + Temperature + Precipitation + Inclination + NDVI + Light \quad (17)$$

$$Soil\ alkalinity = Nitrogen\ deposition \quad (18)$$

$$NDVI = Nitrogen\ deposition + Temperature + Precipitation + Inclination \quad (19)$$

$$Light = NDVI \quad (20)$$

These formulas were implemented and applied to the data using the R-package **brms** (Bürkner 2021). The results are shown in the following tables.

Table 9: SEM Results from applyig the structural equation model depicted in Fig. 3 for the **total species richness** applied to the to the data of the **low and medium-altitude hay meadows** (EUNIS R2.2).
